Paper 0:

OpenEDS: Open Eye Dataset

Introduction

- Eye-tracking is critical for VR/AR, autonomous vehicles, and other key research fields.

- Success of eye tracking ML/DL models is in the quality of the data.

    - Large, high-quality datasets are not prevalent, and existing datasets lack labeling for each eye region.

Figure 1: Examples of the acquired HMD images.

Contribution (& Data)

- The **OpenEDS** (Eye Dataset) is proposed in this work.
- There are 356,649 images in controlled environment.

	Sex		Age					Glasses		#Images			#CT.
	Female	Male	18-23	24-30	31-40	41-50	51-65	No	Yes	SeSeg.	IS.	Seq.	
Train	51	44	3	15	39	26	12	92	3	8,916	193,882	57,000	178
Val.	13	15	1	5	5	8	9	27	1	2,403	57,337	16,800	52
Test	18	11	4	3	7	6	9	27	2	1,440	1,471	17,400	56
Total	82	70	8	23	51	40	30	146	6	12,759	252,690	91,200	286

Table 2: Statistics in OpenEDS for train, validation and test. SeSeg.: Images with semantic segmentation annotations. IS.: Images without annotations. Seq.: Image sequence set. CT: corneal topography. We report #identities regarding demographics (sex, age), wearing glasses or not. We also report #images and #corneal topography (represented as point clouds).

Related Works

- Related eye datasets have large number of images, however are either non-uniform, are not in a controlled lighting environment, or are from too few participants.

- These qualities cause problems training and validating DL models.

Dataset	#Images	#Participants	Resolution	FrameRate	Controlled Light	Sync. Left/Right	Optometric Data
STARE [15]	-	-	-	-	No	No	Yes
PoG [28]	-	20	-	30	Yes	No	No
MASD [7]	2,624	82	-	-	No	No	No
Ubiris v2 [32]	11,102	261	400×300	-	No	-	No
LPW [42]	130,856	22	480×640	95Hz	No	No	No
NVGaze [19]	2,500,000	30	480×640	30Hz	Yes	No	No
Gaze Capture [20]	2,500,000	1,450	Various	-	-	No	No
Ours	356,649	152	400×640	200Hz	Yes	Yes	Yes

Table 1: Publicly available datasets in the field of eye tracking. Note that studies in [20] and [32] offer a large number of participants through crowd-sourcing, where images usually include a large portion of the face and hence lack eye details.

BR = Boundary Refinement
SC = Separable Convolution

Metrics

- Metrics used to evaluate the efficacy of the dataset were extensive. *
- In further evaluation, deep learning models (derived from SegNet) were leveraged to predict eye regions in each image.

Model	Pixel acc.	Mean acc.	Mean F1	Mean IoU	Model Size (MB)	#Param. (M)
mSegnet	98.0	96.8	97.9	90.7	13.3	3.5
mSegnet w/ BR	98.3	97.5	98.3	91.4	13.3	3.5
mSegnet w/ SC	97.6	96.6	97.4	89.5	1.6	0.4

Table 4: Results on semantic segmentation. Model size: size of the PyTorch models on disk. #Params: the number of learnable parameters, where "M" stands for million. *mSegnet*: 4-layer segnet with multiplicative skip connection between the last layer of the encoder and the decoder network

**this explanation should have been better!*

Results

- Results of “challenging samples”:
  - Top: Original image
  - Center: Ground truth
  - Bottom: Predictions from SegNetBR

Eyeglasses | Mascara | Dim light | Varying pupil size

The process of doing gradient descent (math-version)

1. Find the derivative of loss w.r.t to weights over training data

- Plug data into our derivative function, and sum up over data points

The number we'll use to adjust the weight

$$\Delta W = \sum_{i=1}^{n} \frac{\partial J}{\partial W}(x_i,\ y_i)$$

$$\frac{\partial J}{\partial W}(x_i, y_i) = \frac{1}{n}\sum_{i=1}^{n} x_i\left(\hat{y}_i - y_i\right)$$

Derivative of MSE

The process of doing gradient descent (math-version)

2. Adjust the weight by subtracting some amount of
   - (alpha) is known as the *learning rate*
   - It's the first *hyper-parameter* we've seen in the class

$$W := W - \alpha \bullet \Delta W$$

Minus adjusts W in the correct direction

3. Repeat until model is "done training"
   – We can also adjust the learning rate as we train

Adjusting the learning rate

Adjusting the learning rate

Adjusting the learning rate

Gradient Descent

Start with a cost function J():

Then gradually move towards the minimum.

Gradient Descent with Linear Regression

- Now imagine there are two parameters ()
- This is a more complicated surface on which the minimum must be found
- How can we do this without knowing what looks like?

Gradient Descent with Linear Regression

- Compute the gradient, , which points in the direction of the biggest increase!
- - (negative gradient) points to the biggest decrease at that point!

Gradient Descent with Linear Regression

- The gradient is the a vector whose coordinates consist of the partial derivatives of the parameters

$$\nabla J(\beta_0, \ldots, \beta_n) = \; < \frac{\partial J}{\partial \beta_0}, \ldots, \frac{\partial J}{\partial \beta_n} >$$

Gradient Descent with Linear Regression

- Then use the gradient and the cost function to calculate the next point () from the current one (

$$\omega_1 = \omega_0 - \alpha \nabla \frac{1}{2} \sum_{i=1}^{m} \left(\left(\beta_0 + \beta_1 x_{obs}^{(i)} \right) - y_{obs}^{(i)} \right)^2$$

- The learning rate () is a tunable parameter that determines step size

Gradient Descent with Linear Regression

- Each point can be iteratively calculated from the previous one

$$\omega_2 = \omega_1 - \alpha \nabla \frac{1}{2} \sum_{i=1}^{m} \left(\left(\beta_0 + \beta_1 x_{obs}^{(i)} \right) - y_{obs}^{(i)} \right)^2$$

$$\omega_3 = \omega_2 - \alpha \nabla \frac{1}{2} \sum_{i=1}^{m} \left(\left(\beta_0 + \beta_1 x_{obs}^{(i)} \right) - y_{obs}^{(i)} \right)^2$$

Stochastic Gradient Descent

- Use a single data point to determine the gradient and cost function instead of all the data

$$\omega_1 = \omega_0 - \alpha\nabla\frac{1}{2}\cancel{\sum_{i=1}^{m}}\left(\left(\beta_0 + \beta_1 x_{obs}^{(i)}\right) - y_{obs}^{(i)}\right)^2$$

$$\boxed{\omega_1 = \omega_0 - \alpha\nabla\frac{1}{2}\left(\left(\beta_0 + \beta_1 x_{obs}^{(0)}\right) - y_{obs}^{(0)}\right)^2}$$

Stochastic Gradient Descent

- Use a single data point to determine the gradient and cost function instead of all the data

$$\omega_1 = \omega_0 - \alpha \nabla \frac{1}{2}\left(\left(\beta_0 + \beta_1 x_{obs}^{(0)}\right) - y_{obs}^{(0)}\right)^2$$

$$\ldots$$

$$\omega_4 = \omega_3 - \alpha \nabla \frac{1}{2}\left(\left(\beta_0 + \beta_1 x_{obs}^{(3)}\right) - y_{obs}^{(3)}\right)^2$$

- Path is less direct due to noise in single data point—"stochastic"

Mini Batch Gradient Descent

- Perform an update for every training examples

$$\omega_1 = \omega_0 - \alpha \nabla \frac{1}{2} \sum_{i=1}^{n} \left(\left(\beta_0 + \beta_1 x_{obs}^{(i)} \right) - y_{obs}^{(i)} \right)^2$$

Best of both worlds:

- Reduced memory relative to "vanilla" gradient descent
- Less noisy than stochastic gradient descent

Motivation

Motivation

- Curse of dimensionality

- Local Constancy & Smoothness Regularization

- Manifold Learning

Implementation

Let’s start with regression

Regression

- Modeling the relationship between a scalar response and one or more explanatory variables.
    - One explanatory variables = **linear regression**
    - Multiple explanatory variables = **multivariate regression**
- Predictions of…
    - Price of an item, based upon the market analysis
    - Salary, based upon company salaries, their experience, ..
    - Score of a sporting event, based on team analytics
    - GDP growth, based on consumer data

Regression

How does it work?

- Linear Regression
  - Least Squares method
    - Published by Legendre (1805) and Gauss (1809)
    - Variations: Ordinary, Weighted, Generalized

$$\mathrm{MSE}_{\text{test}} = \frac{1}{m}\sum_i (\hat{\boldsymbol{y}}^{(\text{test})} - \boldsymbol{y}^{(\text{test})})_i^2$$

TensorFlow

What is TensorFlow?

- A **framework** provided by Google for math using **computation graphs**.
    - Specific features for machine learning
- **Primary interface**: Python
    - Integrates with NumPy
- **Implementation**: C++ & CUDA
    - Designed to be flexible, scalable, & deployable

TF History

- Google's successor to DistBelief
- Timeline:
  - Nov 2015: Open source implementation released
  - Feb 2016: TensorFlow Serving
  - Apr 2016: Distributed runtime
  - Jan 2017: XLA (Accelerated Linear Algebra)
  - Feb 2017: TensorFlow Fold
- *Backwards compatibility promised between releases (i.e. 1.0.0 until 2.0.0)*

https://www.tensorflow.org/api_docs/python/tf

Computation Graphs

Getting Started: TensorFlow

<u>Two-step programming pattern:</u>

1. Define the computation graph

2. Run the graph

TF 1. Define Computation Graph

TensorFlow API classes:

Graph Container for the operations & tensors..

```
import tensorflow as tf
```

Operation Nodes in the graph, representing computations

```
a = tf.constant( 3.0, name="input1" )
b = tf.constant( 2.0, name="input2" )
```

Or, instead of hard-coding, use a placeholder:

```
a = tf.placeholder( tf.float32, name="input1" )
```

Tensor Edges in the graph, representing data

```
c = tf.add( a, b, name="my_add_op" )
d = tf.multiply( a, c, name="my_mul_op" )
```

TF 2. Run Computation Graph

TensorFlow API classes:

Session objects are dedicated to a single graph for execution.

```
sess = tf.Session()
```

Placeholders contain data - a dictionary mapping Tensor keys to numeric values.

```
feed_dict = {a:3.0, b:2.0}
```

Fetches tells TF what outputs we want (a Tensor, Operation, or list of them)

```
out = sess.run( d, feed_dict=feed_dict )
```

TensorFlow Variables

For **stateful information**, use **`Variable`** objects

```
store = tf.Variable( 0.0, name="var" )
```

Create operations to update these values.

```
inc = store.assign( store + 1 )
```

Variables are not established in the Session until initialized.

```
init = tf.global_variables_initializer()

sess.run( init )
```

Machine Learning & TensorFlow

Cost Function for Linear Regression

For our previously defined model

$$\hat{y}_i = Wx_i + b$$

Establish **cost function J** via mean squared errors (MSE)

$$\mathrm{J} = \frac{1}{2n} \sum_{i=1}^{n} \left(\hat{y}_i - y_i \right)^2$$

n = # training examples
W = weights
x = input
y = output
b = bias
J = cost function

Minimizing Loss

To minimize this cost, take the derivative:

$$\mathrm{J} = \frac{1}{2n}\sum_{i=1}^{n}\left(\hat{y}_i - y_i\right)^2$$

$$= \frac{1}{2n}\sum_{i=1}^{n}\left((Wx_i + b) - y_i\right)^2$$

$$\frac{\partial J}{\partial W} = \frac{1}{n}\sum_{i=1}^{n} x_i\left(\hat{y}_i - y_i\right)$$

$$\frac{\partial J}{\partial b} = \frac{1}{n}\sum_{i=1}^{n}\left(\hat{y}_i - y_i\right)$$

n = # training examples
W = weights
x = input
y = output
b = bias
J = cost function

Minimizing Loss

In linear regression, we can use linear algebra..

$$W = (X^T X)^{-1} X^T Y$$

Problems:

- For large input (X), computing the inverse is difficult
- Inverse function is ill-conditioned
- Not all models will have a closed-form solution

n = # training examples
W = weights
x = input
y = output
b = bias
J = cost function

Process of gradient decent (computation graph)

1. Start with our basic model

Process of gradient decent (computation graph)

2. Define our cost function
   - In this case `tf.square(add – y)`
   - Built in: `tf.squared_difference(add, y)`

Process of gradient decent (computation graph)

3. Get the derivatives of the cost w.r.t Variables
   - Sum over all examples =

Process of doing gradient decent (computation graph)

4. Use derivatives and learning rate to update Variables

Cost needs to be defined like other operations in TF

```
cost = tf.reduce_mean(tf.squared_difference(add, Y))
```

Derivatives and updates use a `tf.Optimizer`

`Optimizer` computes derivatives and applies them to **`Variables`**
